

# File Systems

\* Old OS: before bytes, files were a sequence of **records**

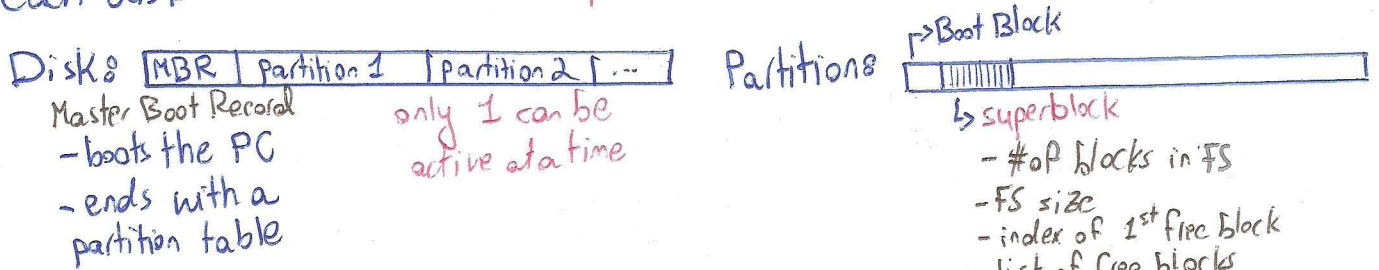

\* Files: • regular files • special files  
 ASCII readable    Binary executable    char(byte) I/O    Block hard drive

\* File access: • sequential  
 must go in order (magnetic tape)

• random  
 can access any part

• Directories: files that organize a hierarchy of other files

\* UNIX sees the disk as a sequence of **physical blocks** of fixed size.  
 each disk can be divided into **partitions** each with its own file system.

## Disk Allocation Layouts:

1- Contiguous: Store each file as a contiguous set of physical data blocks

adv: - quick & easy to find block holding my data  
 - almost no seek required for sequential data.  
 - excellent file reading performance

disadv: - file grows  $\Rightarrow$  may have to move it.  
 - internal fragmentation inside a single block  
 - external fragmentation between files

2- Linked List: the first word of each block contains the address of the next block

adv: - no more variable sized file allocation  
 - no external fragmentation.

disadv: - terrible performance in some cases  
 - long seek time  
 - amount of data per block is no longer a power of 2

3- Linked List with File Allocation Table (FAT): one entry per physical block

The table is loaded into memory on fs boot.

used next

adv: - size of block is full (of data)

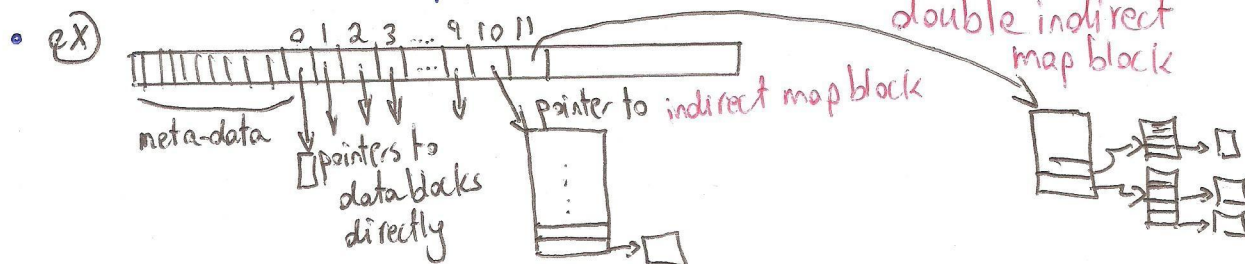

- random access much easier since entire chain is in the memory.

disadv: - entire table must be in memory at all times.

4 - inode s: (UNIX) a data structure associated with the file.

open file  $\Rightarrow$  store in inode and release when closed.

The inode contains - management (metadata)  
- paths to data blocks

1 KB block & 4B pointer (entry)

$\Rightarrow 1\text{KB}/4 = 256$  entries in map block

0  $\rightarrow$  9: 1KB each  $\Rightarrow$  10KB

if file > 10KB  $\Rightarrow$  use 10

10: 256 entries  $\Rightarrow$  256 KB

if file > 266 KB  $\Rightarrow$  use 11

11:  $(256)^2$  KB

12:  $(256)^3$  KB

$\Rightarrow$  if we go up to

12 we can store

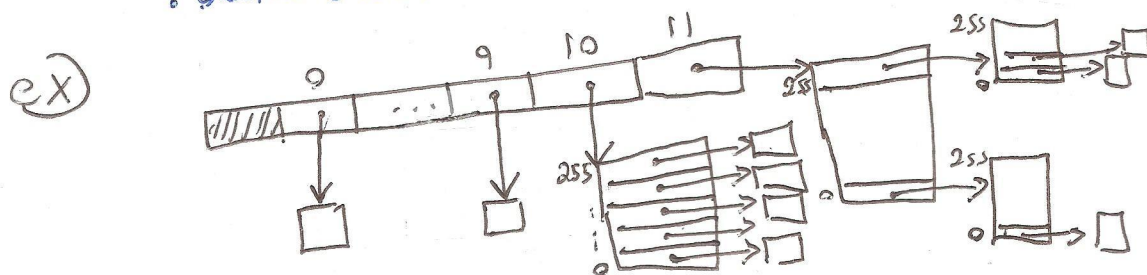

$10\text{KB} + 256\text{KB} + 256^2\text{KB}$   
 $+ 256^3\text{KB} \approx 16\text{GB}$

max file size

• Effective size of file = (#map blocks  $\times$  block size)  
+ (#data blocks  $\times$  block size)  
+ size(inode)

Notes: map block: blocks that **hold tables**

data block: blocks that hold data.

data blocks:  $0-9$  10 +  $256$  +  $256^2$

map blocks: **1 + 1 + 256**
